Practical IV

Roll No.: T055	Name: Achal Yadav
Class: TYIT	Batch: 1
Date of Assignment: 25-07-2026	Date/Time of Submission: 25-07-2026

Aim:-Bayes' Rule Application

1. Scenario:

A medical test is used to detect a particular disease.

The probability that a randomly selected person has the disease is 1%.

If a person has the disease, the test returns positive with probability 99%.

If a person does not have the disease, the test still returns positive with probability 5% (false positive rate).

A person takes the test and receives a positive result.

Problem Statement:

Write a Python program to compute the probability that the person actually has the disease given that the test result is positive.

Code:-

```
P_D = 0.01
P_Pos_D = 0.99
P_Pos_NotD = 0.05
P_NotD=1-P_D
P_D_Pos = (P_Pos_D* P_D) / ((P_Pos_D* P_D) + (P_Pos_NotD * P_NotD))
print("Probability that person actually has disease:")
print(round(P_D_Pos * 100, 2), "%")
```

Output:-

```
Probability that person actually has disease:
16.67 %
```
